Introduction

Technical environmental reports that discuss soil, water, or air contamination often report numerical values in units unfamiliar to the general public. The different units of measurement can be confusing. This fact sheet helps people understand these measurement units. Examples of typical units of measurement are listed below.

**Numbers**
- Million = 1,000,000
- Billion = 1,000,000,000
- Trillion = 1,000,000,000,000
- One millionth = 0.000001
- One billionth = 0.000000001

**Mass**
- 28 grams = about 1 ounce
- 1 kilogram (kg) = 1,000 grams
- 1 milligram (mg) = 1/1,000 gram = 0.001 gram
- 1 microgram (µg) = 1/1,000,000 gram = 0.000001 gram
- 1 nanogram (ng) = 1/1,000,000,000 gram = 0.000000001 gram
- 1 picogram (pg) = 1/1,000,000,000,000 gram = 0.000000000001 gram

**Volume**
- One liter (L) = 1.06 quarts
- One cubic meter (m³) = 35.31 cubic feet (ft³)
- One cubic meter (m³) = 1,000 liters (L)
- One liter (L) = 1,000 milliliters (ml) = 1,000 cubic centimeters

Concentrations in Soil and Water

Concentrations of chemicals in soil are typically measured in units of the mass of chemical (milligrams, mg, or micrograms, µg) per mass of soil (kilogram, kg). This is written as mg/kg or µg/kg. Sometimes concentrations in soil are reported as parts per million (ppm) or parts per billion (ppb). Parts per million and parts per billion may be converted from one to the other using this relationship: 1 part per million = 1,000 parts per billion.

For soil, 1 ppm = 1 mg/kg of contaminant in soil, and 1 ppb = 1 µg/kg. A measurement of 6 mg/kg is the same as 6 ppm or 6,000 ppb, which is equal to 6,000 µg/kg.

Concentrations of chemicals in water are typically measured in units of the mass of chemical (milligrams, mg, or micrograms, µg) per volume of water (liter, L, l). Concentrations in water can also be expressed as parts per million (ppm) or parts per billion (ppb). Parts per million and parts per billion may be converted from one to the other using this relationship: 1 part per million = 1,000 parts per billion.

For water, 1 ppm = about 1 mg/L (also written as mg/l) of contaminant in water, and 1 ppb = 1 µg/L (also written as µg/l). A measurement of 6 mg/L is the same as 6 ppm or 6,000 ppb, which is equal to 6,000 µg/L.

Occasionally, concentrations of chemicals in water may be written as grams per cubic meter (g/m³). This is the same as grams per 1,000 liters, which may be converted to milligrams per liter (mg/L). Therefore, 1 g/m³ = 1 mg/L = 1
ppm. Likewise, one milligram per cubic meter (mg/m³) is the same concentration in water as one microgram per liter (µg/L), which is about 1 ppb.

**Concentrations in Air**

Concentrations of chemicals in air are typically measured in units of the mass of chemical (milligrams, micrograms, nanograms or picograms) per volume of air (cubic meter or cubic feet). However, concentrations may also be expressed as parts per million (ppm) or parts per billion (ppb) by using a conversion factor. The conversion factor is based on the molecular weight of the chemical and is different for each chemical. Also, atmospheric temperature and pressure affect the calculation.

Typically, conversions for chemicals in air are made assuming a pressure of 1 atmosphere and a temperature of 25 degrees Celsius. For these conditions, the equation to convert from concentration in parts per million to concentration in milligrams per cubic meter (mg/m³) is:

\[
\text{Concentration (mg/m³)} = 0.0409 \times \text{concentration (ppm)} \times \text{molecular weight}
\]

To convert from mg/m³ to ppm, the equation is:

\[
\text{Concentration (ppm)} = \frac{24.45 \times \text{concentration (mg/m³)}}{\text{molecular weight}}
\]

The same equations may be used to convert micrograms per cubic meter (µg/m³) to parts per billion (ppb) and vice versa:

\[
\text{Concentration (µg/m³)} = 0.0009 \times \text{concentration (ppb)} \times \text{molecular weight}
\]

Or, concentration (ppb) = \(24.45 \times \text{concentration (µg/m³)} \div \text{molecular weight}\)

**Note:** Sometimes chemical concentrations in air are given in concentration per cubic feet (ft³) instead of concentration per cubic meter (m³). The conversion from cubic feet to cubic meter and vice versa is 1 ft³ = 0.02832 m³ and 1 m³ = 35.31 ft³.

**Conversion Example**

The molecular weight of benzene is 78. If the concentration of benzene in air is 10 mg/m³, convert to the units of ppm by multiplying 24.45 by 10 mg/m³ and dividing by 78, which equals 3.13 ppm.

**Radioactivity**

Radioactivity is the process of one element decaying to form another element. This rate of decay (activity) is commonly measured in units of picocuries (pCi) or millibecquerels (mBq).

1 pCi = 37 mBq

Picocuries or millibecquerels are related to the decay rate, or disintegration rate of an element, as follows:

1 picocurie = 2.2 disintegrations per minute (dpm)  
37 mBq = 2.2 disintegrations per minute

Therefore, 1 pCi or 37 mBq is equivalent of 2.2 atoms of one element decaying into another element. To put this number in perspective, the average indoor radon level is 1.3 pCi/L and average outdoor radon level is 0.4 pCi/L. Radon is a radioactive gas that occurs naturally. Some radiation monitors measure radioactivity in counts per minute (cpm), usually counts of alpha particles or beta particles. The equipment does not measure the actual disintegrations per minute at the source of the radioactivity. Calibrating and converting cpm to dpm is specific for each instrument.

**Measuring the Effect of Radioactivity**

The measure of radioactivity in pCi or mBq is used in complex calculations to determine the amount of ionizing radiation that human tissue will absorb when exposed to specific radioactive materials. This section describes units
associated with measuring the effect of radioactivity on human tissue. It is adapted from information provided by the Nuclear Regulatory Commission (http://www.nrc.gov/about-nrc/radiation/health-effects/measuring-radiation.html). There are four different but interrelated units of measure: radioactivity, exposure, absorbed dose and dose equivalent. These can be remembered by the mnemonic **R-E-A-D**, as follows, with both common (British, e.g., Ci) and international (metric, e.g., Bq) units in use:

**R** → Radioactivity refers to the amount of ionizing radiation released by a material (charged particles). Whether it emits alpha or beta particles, gamma rays, x-rays or neutrons, a quantity of radioactive material is expressed in terms of its radioactivity (or simply its activity), which represents how many atoms in the material decay in a given time period. The units of measure for radioactivity are the curie (Ci) and becquerel (Bq) or picocurie (pCi) and millibecquerel (mBq). [1 Ci = 0.037 Bq]

**E** → Exposure describes the amount of radiation traveling through the air. It is a measure of the ionizations of the molecules in a mass of air. Many radiation monitors measure exposure. The units for exposure are the roentgen (R) and coulomb/kilogram (C/kg). R can only be used to describe an amount of gamma and x-rays, and only in air. One R is equal to depositing in dry air enough energy to cause 0.000258 coulombs per kilogram (C/kg) of energy. [1 R = 0.000258 C/kg]

**A** → Absorbed dose describes the amount of radiation absorbed by an object or person (that is, the amount of energy that radioactive sources deposit in materials through which they pass). The units for absorbed dose are the radiation absorbed dose (rad) and gray (Gy). One rad equals the absorption of 100 ergs (ergs) of energy per gram of material. One gray equals the absorption of 1 Joule (J) of energy per kilogram of material.

\[
1 \text{ rad} = 100 \text{ ergs per gram} \quad 1 \text{ J} = 10,000,000 \text{ ergs}
\]

\[
1 \text{ Gy} = 1 \text{ J/kg} \quad 1 \text{ Gy} = 100 \text{ rad}
\]

**D** → Dose equivalent (or effective dose) combines the amount of radiation absorbed and the medical effects of that type of radiation. For beta and gamma radiation, the dose equivalent is the same as the absorbed dose. By contrast, the dose equivalent is larger than the absorbed dose for alpha and neutron radiation, because these types of radiation are more damaging to the human body. Units for dose equivalent are the roentgen equivalent man (rem) and sievert (Sv). Biological dose equivalents are commonly measured in 1/1000th of a rem (known as a millirem or mrem). [1 Sv = 100 rem; 1 mSv = 100 mrem]

Table 1 shows some typical radiation doses in the United States.

<table>
<thead>
<tr>
<th>Source</th>
<th>Dose Equivalent</th>
